

## NAME

bytes - Perl pragma to force byte semantics rather than character semantics

## SYNOPSIS

```
use bytes;
... chr(...);      # or bytes::chr
... index(...);    # or bytes::index
... length(...);   # or bytes::length
... ord(...);     # or bytes::ord
... rindex(...);  # or bytes::rindex
... substr(...);  # or bytes::substr
no bytes;
```

## DESCRIPTION

The `use bytes` pragma disables character semantics for the rest of the lexical scope in which it appears. `no bytes` can be used to reverse the effect of `use bytes` within the current lexical scope.

Perl normally assumes character semantics in the presence of character data (i.e. data that has come from a source that has been marked as being of a particular character encoding). When `use bytes` is in effect, the encoding is temporarily ignored, and each string is treated as a series of bytes.

As an example, when Perl sees `$x = chr(400)`, it encodes the character in UTF-8 and stores it in `$x`. Then it is marked as character data, so, for instance, `length $x` returns 1. However, in the scope of the `bytes` pragma, `$x` is treated as a series of bytes - the bytes that make up the UTF8 encoding - and `length $x` returns 2:

```
$x = chr(400);
print "Length is ", length $x, "\n";      # "Length is 1"
printf "Contents are %vd\n", $x;         # "Contents are 400"
{
    use bytes; # or "require bytes; bytes::length()"
    print "Length is ", length $x, "\n"; # "Length is 2"
    printf "Contents are %vd\n", $x;     # "Contents are 198.144"
}
```

`chr()`, `ord()`, `substr()`, `index()` and `rindex()` behave similarly.

For more on the implications and differences between character semantics and byte semantics, see *perluniintro* and *perlunicode*.

## LIMITATIONS

`bytes::substr()` does not work as an `lvalue()`.
